Dermal Fillers

Fillers for your Feet

In podiatry, dermal fillers are predominantly used for cosmetic treatments to plump up and give instant pain relief to the bottom of the foot. The most common example is to provide cushioning for a reoccurring or persistent corn.

What are Dermal Fillers?

They are gels of various thicknesses which are made from hyaluronic acid (HA) or poly-L-lactic-acid. HA develops by natural means within the body, existing in the skin, joints and eyes. It is hydrophilic, which means it draws in water molecules to 'plump' up, cushion, and keep structures resilient and flexible. It is an organic compound which over time normally deteriorates. The effects can last up 6-8 months then naturally break down by the body over time

What are they used to Treat?

- Bony prominences
- Painful corns
- Fat pad atrophy
- Hammer toes
